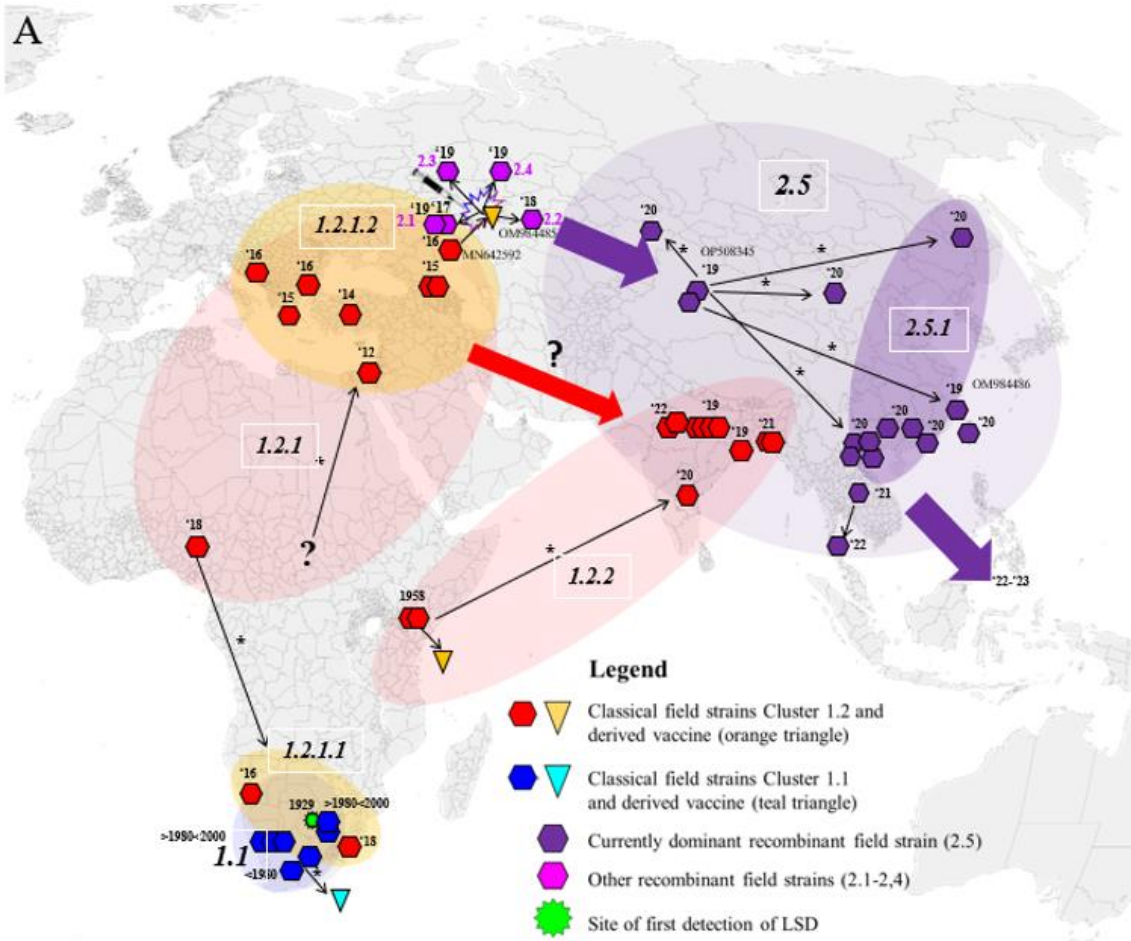
Lumpy Skin Disease Virus Genome Sequence Analysis: Putative Spatio-Temporal Epidemiology, Single Gene versus Whole Genome Phylogeny and Genomic Evolution

Floris C. Breman *, Andy Haegeman, Nina Krešić, Wannes Philips and Nick De Regge



Pathogenesis

- Disease severity varies between animals

severe LSD cases – mild LSD cases – subclinical animals – no productive infection

- 30 to 50% diseased animals in experimental settings
- Morbidity: 10 to 45%; Mortality: 1-5%
- Self limiting disease
- No-carrier status, no latency

Differential diagnosis

- Bovine herpes mammillitis (=pseudo-lumpy skin disease) (bovine herpesvirus 2)
- Bovine papular stomatitis (parapoxvirus)
- Pseudocowpox (parapoxvirus)
- Vaccinia virus and cowpox virus (orthopoxvirus)
- Dermatophilosis
- Demodicosis
- Insect bites, tick bites
- Besnoitiosis
- Rinderpest
- Hypoderma bovis infection
- Photosensitization
- Urticaria
- Onchocercosis

Bovine herpesvirus 2

Bovine popular stomatitis

Pseudocowpox

- Clinical diagnosis: passive and active surveillance; not always straightforward, mild cases, asymptomatic cases, production system, other pathogens, …
- Importance of laboratory diagnosis

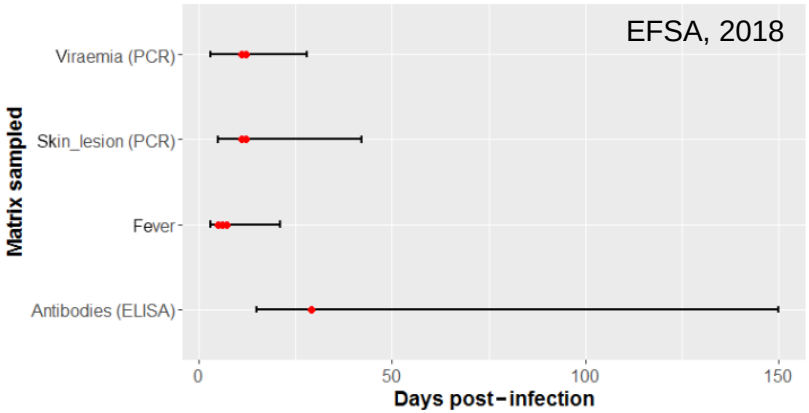
LSDV diagnosis: sample selection

Diagnostic samples: blood, saliva, ocular-nasal discharge, nodules, scabs, crusts, semen

✓ Wound crusts → **Ideal to confirm clinical picture**

- High viral load, long time positive
- Suited for virus isolation and PCR
- Easy to collect
- No need for the most sensitive test

- High risk of contamination
- Extra care is needed in sampling and handling
- Change gloves, also during field collection



✓ Nodule and skin lesion

- Similar remarks as wound crusts
- Need to take a biopt, change biopsy needles

✓ EDTA blood

- Suited for virus isolation and PCR
- Easy to collect

- Viremia is limited in time and often low
- More sensitive tests are needed

✓ Swabs (buccal, nasal)

- Similar remarks as for blood
- Potential for environmental contamination
- Risky to determine individual status

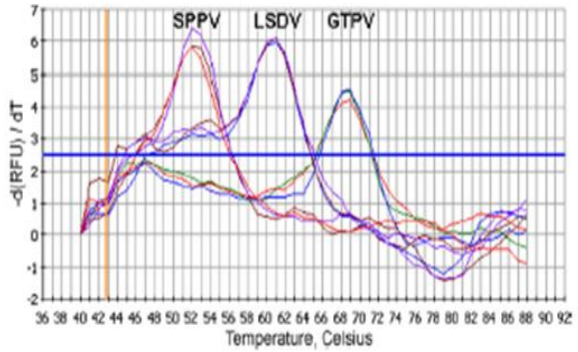
poxvirus infection

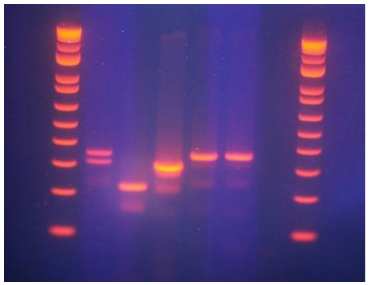
Live virus can be isolated	Time
Skin nodules	39 days
Dried scabs	Several years if kept at -20°C
Blood	5-16 days
Saliva and nasal discharge	At least 21 days
Eye discharge	Duration of infectivity not known
Semen	22 days to 42 days
Milk	Duration of infectivity not known
Urine and feces	Duration of infectivity not known

(Babiuk, 2008, Dietze *et al.*, 2018, Irons *et al.*, 2005, Tuppurainen *et al.*, 2005, Weis, 1968)

Laboratory diagnosis - virology

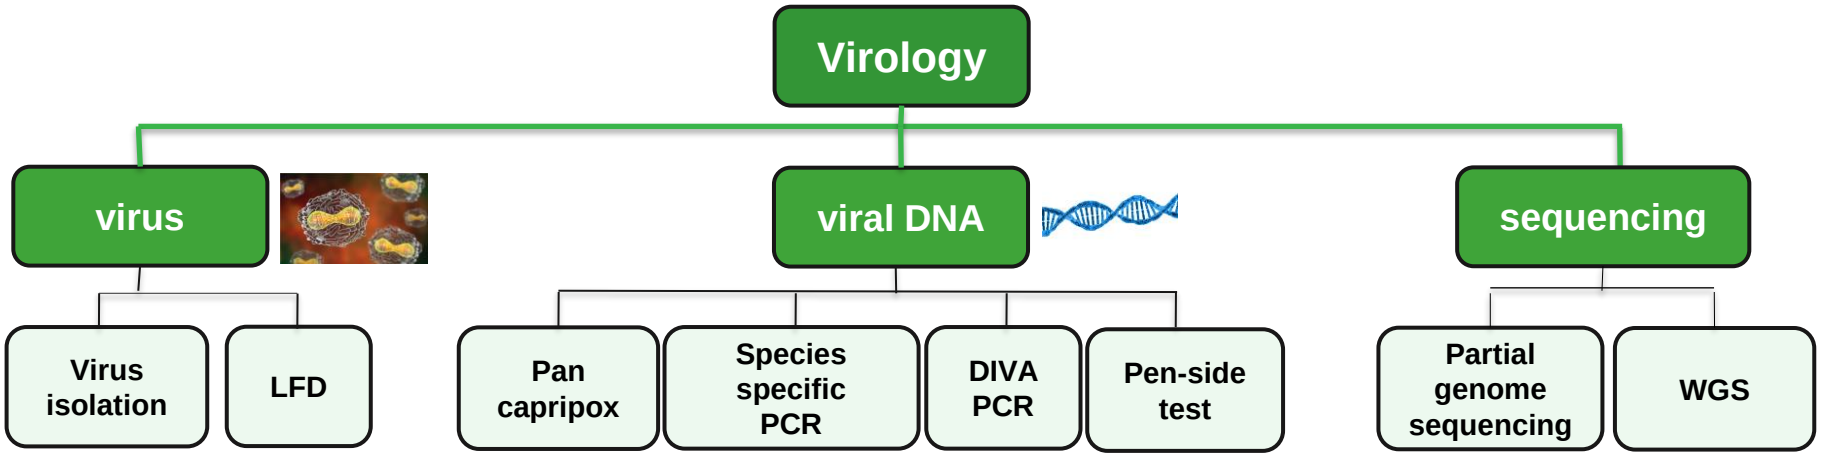
- **Virology**
  - **virus** 
    - Virus isolation
    - LFD
  - **viral DNA** 
    - Pan capripox
    - Species specific PCR
    - DIVA PCR
    - Pen-side test
  - **sequencing**
    - Partial genome sequencing
    - WGS





1kb ladder
1. Lumpivax vaccine
2. SPPV RM65 vaccine
3. Field type SPPV
4. Field type LSDV
5. LSDV vaccine (Neehtling)
6 Neg
1kb ladder

Laboratory diagnosis - virology



pan capripox PCR assays

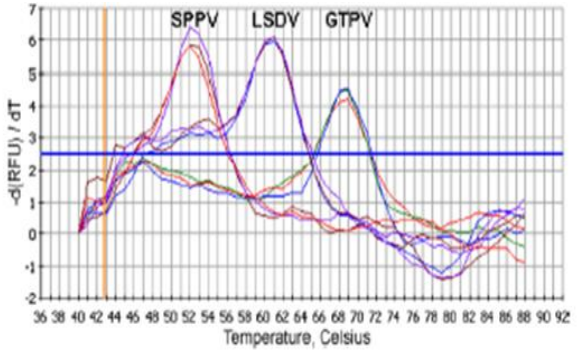
- Detect LSDV, SPPV, GTPV

- Bowden et al, 2008
- Haegeman et al, 2013
- ID.Vet capripox triplex assay

Species specific PCR assays

- Differentiates between LSDV, SPPV and GTPV

- Lamien et al, 2011
- Wolff et al, 2021
- Galaye et al, 2015 & 2017



Laboratory diagnosis – DIVA PCRs

DIVA PCRs are important to differentiate adverse reactions after vaccination from clinical disease induced by virulent field strains:

- Multiple DIVA PCRs exist
- All have specific set-up, fit for purpose in specific epidemiological context
- DIVA test selection depends on knowledge of locally circulating strains
- 2.5 recombinant strains seem predominant in SE Asian epidemic →

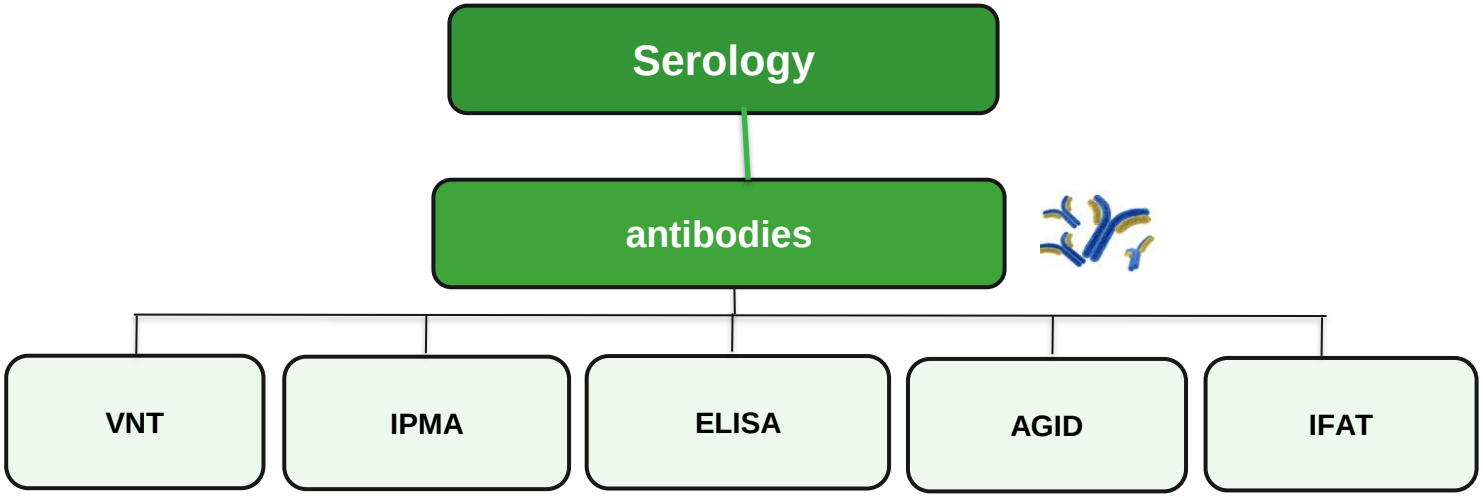
Laboratory diagnosis - serology

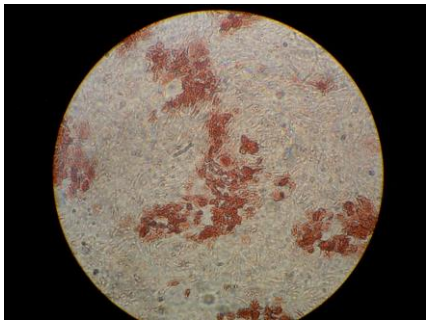
✓ Serum/serology

- Easy to collect
- Antibodies can remain present for a prolonged period of time
- Suitable for screening/surveillance/post-vaccination monitoring

- Not suitable for early detection
- Can take multiple weeks before seroconversion is detected
- Depends on the method used

Laboratory diagnosis - serology



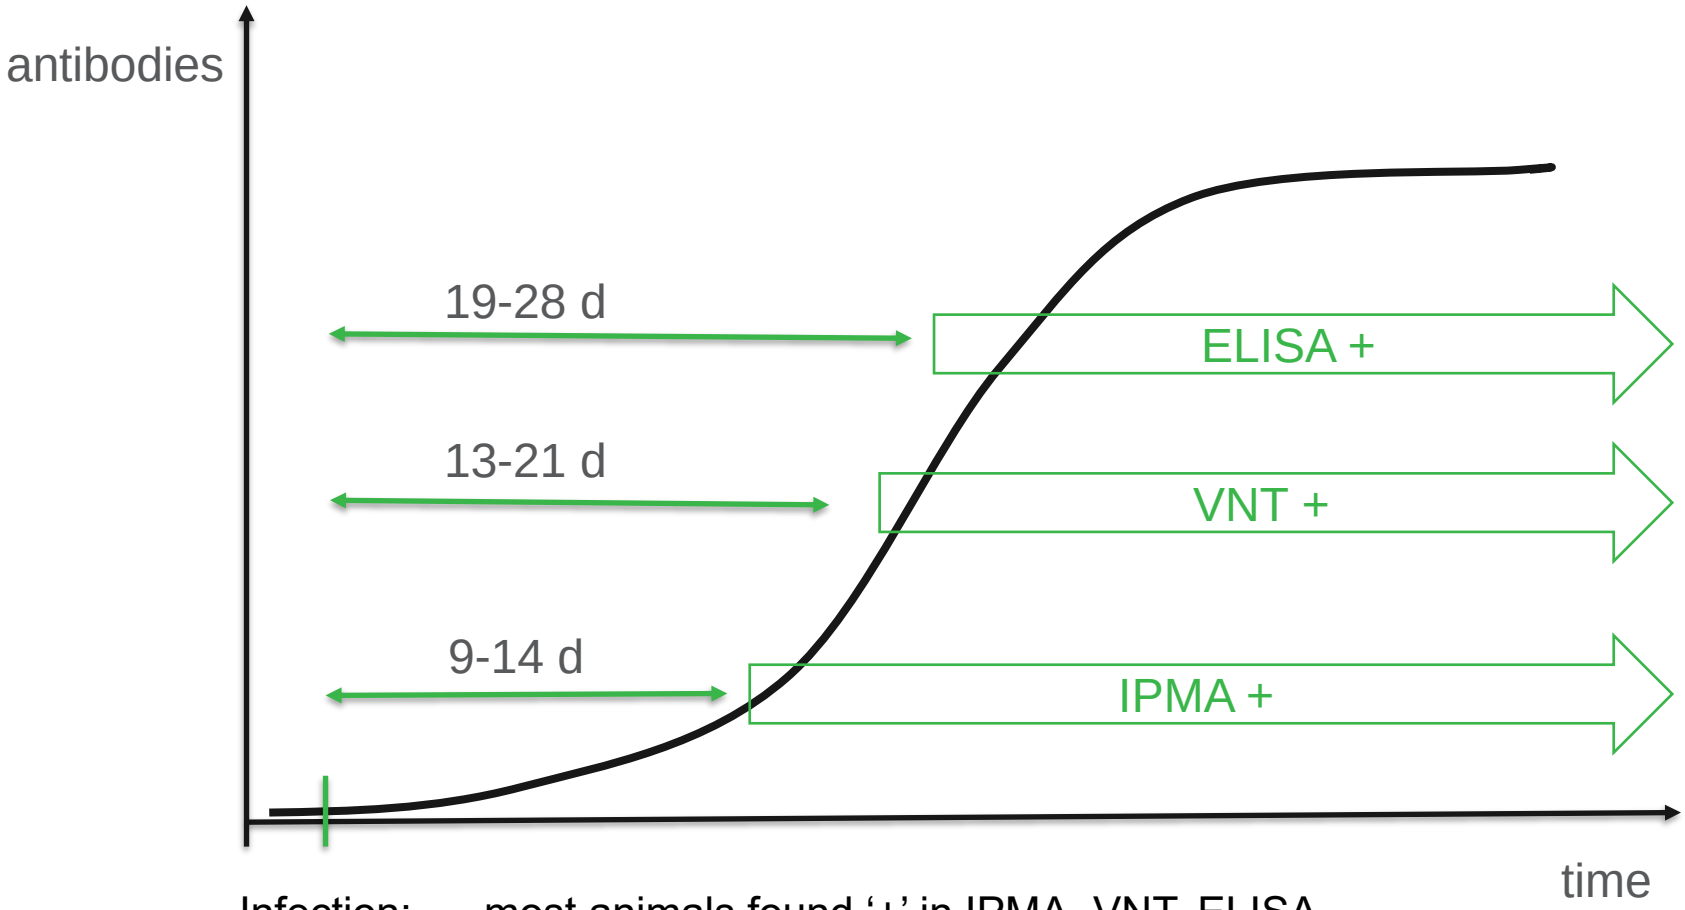


Laboratory diagnosis - serology

Test	Advantages	Disadvantages
VNT	- Reliable (gold standard) - 2 approaches	- Live virus - Time and costs - CPE effect ! Not virus specific
IPMA	- Early detection - Fast results if plates prepared - Highly sensitivity	- Experience - Live virus - More sensitive to sample quality
ELISA	- Commercially available - Easy to do - High throughput - Good sensitivity / specificity	- Less sensitive then VNT and IPMA, not for early detection
Western Blot	- High specific - High sensitive	- Difficult - Expensive
IFAT	- High sensitivity - Flexible (other dyes/microscopes)	- Cross reaction - Time and costs

LSDV diagnostics: serology

Virus neutralization tests – IPMA – ELISA



Infection: most animals found '+' in IPMA, VNT, ELISA

Vaccination: most animals found '+' in IPMA, VNT; only +/- 50% '+' in ELISA

LSDV diagnostics: serology

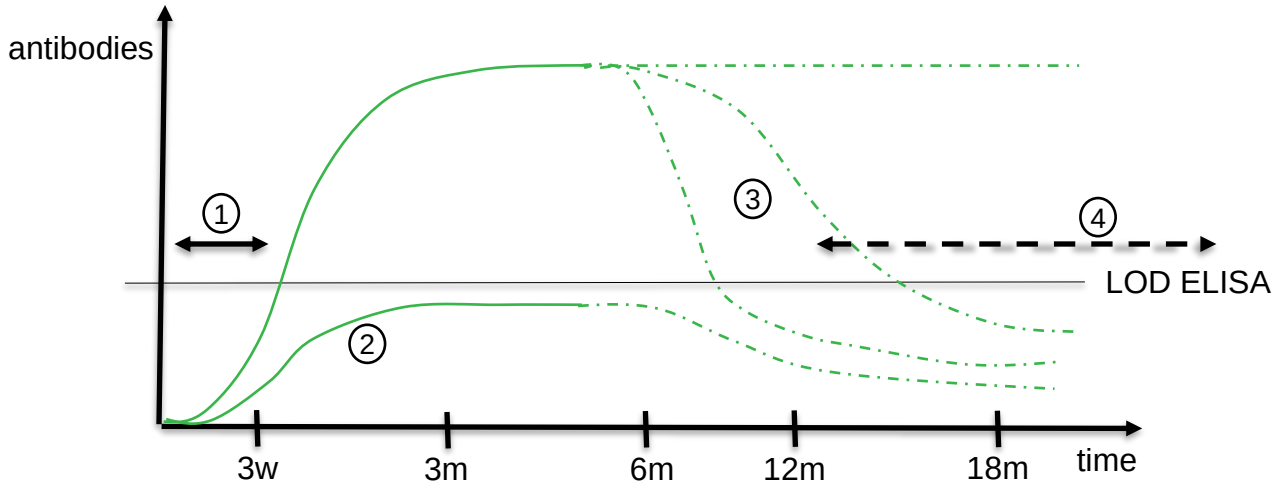
Post vaccination monitoring

- No DIVA vaccines available – vaccinated and infected animals cannot be differentiated based on serology
- Important to keep good and complete records of vaccinated animals
- Important to implement passive and active LSDV clinical surveillance upon vaccination to ensure early detection of new cases
- Limitations for serological surveillance for post vaccination monitoring

Post vaccination monitoring



1. ELISA is most convenient test for PVM, but only around 50% of vaccinated animals develop antibody levels above the LOD of the commercial ELISA. 2 to 3 months post vaccination is best moment to measure efficacy of LSD vaccination

2. Vaccine induced antibodies might disappear over time although ELISA positive animals have been detected at 18m post vaccination under experimental conditions (unpublished EURL results)

3. Protection against challenge is not dependent on ELISA antibody detection in challenged animals, indicating role of CMI.
